1

$OABC$  is the cross-section through the centre of mass of a uniform prism of weight  $20$  N. The cross-section is in the shape of a sector of a circle with centre  $O$ , radius  $OA = r$  m and angle  $AOC = \frac{2}{3}\pi$  radians. The prism lies on a plane inclined at an angle  $\theta$  radians to the horizontal, where  $\theta < \frac{1}{3}\pi$ .  $OC$  lies along a line of greatest slope with  $O$  higher than  $C$ . The prism is freely hinged to the plane at  $O$ . A force of magnitude  $15$  N acts at  $A$ , in a direction towards to the plane and at right angles to it (see diagram). Given that the prism remains in equilibrium, find the set of possible values of  $\theta$ . [9]

2 A uniform semicircular lamina of radius  $0.25$  m has diameter  $AB$ . It is freely suspended at  $A$  from a fixed point and hangs in equilibrium.

(i) Find the distance of the centre of mass of the lamina from the diameter  $AB$ . [1]

(ii) Calculate the angle which the diameter  $AB$  makes with the vertical. [2]

The lamina is now held in equilibrium with the diameter  $AB$  vertical by means of a force applied at  $B$ . This force has magnitude  $6$  N and acts at  $45^\circ$  to the upward vertical in the plane of the lamina.

(iii) Calculate the weight of the lamina. [3]

3

A uniform solid cone of height  $0.6\text{ m}$  and mass  $0.5\text{ kg}$  has its axis of symmetry vertical and its vertex  $V$  uppermost. The semi-vertical angle of the cone is  $60^\circ$  and the surface is smooth. The cone is fixed to a horizontal surface. A particle  $P$  of mass  $0.2\text{ kg}$  is connected to  $V$  by a light inextensible string of length  $0.4\text{ m}$  (see diagram).

- (i) Calculate the height, above the horizontal surface, of the centre of mass of the cone with the particle. [3]

$P$  is set in motion, and moves with angular speed  $4\text{ rad s}^{-1}$  in a circular path on the surface of the cone.

- (ii) Show that the tension in the string is  $1.96\text{ N}$ , and calculate the magnitude of the force exerted on  $P$  by the cone. [5]
- (iii) Find the speed of  $P$ . [1]

4

A uniform solid cone of height 1.2 m and semi-vertical angle  $\theta^\circ$  is divided into two parts by a cut parallel to and 0.4 m from the circular base. The upper conical part,  $C$ , has weight 16 N, and the lower part,  $L$ , has weight 38 N. The two parts of the solid rest in equilibrium with the larger plane face of  $L$  on a horizontal surface and the smaller plane face of  $L$  covered by the base of  $C$  (see diagram).

- (i) Calculate the distance of the centre of mass of  $L$  from its larger plane face. [3]

An increasing horizontal force is applied to the vertex of  $C$ . Equilibrium is broken when the magnitude of this force first exceeds 4 N, and  $C$  begins to slide on  $L$ .

- (ii) By considering the forces on  $C$ ,
- (a) find the coefficient of friction between  $C$  and  $L$ , [1]
- (b) show that  $\theta > 14.0$ , correct to 3 significant figures. [2]

$C$  is removed and  $L$  is placed with its curved surface on the horizontal surface.

- (iii) Given that  $L$  is on the point of toppling, calculate  $\theta$ . [3]

5

A uniform rod  $AB$  has weight  $6\text{ N}$  and length  $0.8\text{ m}$ . The rod rests in limiting equilibrium with  $B$  in contact with a rough horizontal surface and  $AB$  inclined at  $60^\circ$  to the horizontal. Equilibrium is maintained by a force, in the vertical plane containing  $AB$ , acting at  $A$  at an angle of  $45^\circ$  to  $AB$  (see diagram). Calculate

- (i) the magnitude of the force applied at  $A$ , [3]
- (ii) the least possible value of the coefficient of friction at  $B$ . [4]

6

A circular object is formed from a uniform semicircular lamina of weight  $12\text{ N}$  and a uniform semicircular arc of weight  $8\text{ N}$ . The lamina and the arc both have centre  $O$  and radius  $0.6\text{ m}$  and are joined at the ends of their common diameter  $AB$ . The object is freely pivoted to a fixed point at  $A$  with  $AB$  inclined at  $30^\circ$  to the vertical. The object is in equilibrium acted on by a horizontal force of magnitude  $F\text{ N}$  applied at the lowest point of the object, and acting in the plane of the object (see diagram).

- (i) Show that the centre of mass of the object is at  $O$ . [3]
- (ii) Calculate  $F$ . [3]
